VECTOR INERT RADIAL
(hyper telescope)

by

Philip Mazeikas

CONCEPT:

The displaced function of inverse dimensional axis derives instantaneous frequency.

BLUEPRINT:

The displaced sequence beyond a incongruent lapse upon the differential of static remission of interval of longitudinal axis of derivative determines the instantaneous invariable release upon the threshold of displaced frequency of differential sequence determined by the longitudinal limit designated upon the threshold of instantaneous pressure.

SYNOPSIS:

The incongruent and displaced measure of congruent displaced variable static of frame of longitudinal axis determines the measure.

SCHEMATIC:

AXIS
"interval"
→
CELL
"determined variance"
→
MEGAWATT
"derivative"
→
LENS
"invariable measure"
→
MAGNET
"dimensional limit"
→
VOLT
"threshold"
→
DELTA WAVE
"inversion"

DESIGN:

The axis designates field upon invariable return of longitudinal pressure. The cell derives instantaneous threshold of congruent variance. The megawatt designates field upon static derivative of invariable frequency. The lens defines instantaneous inert pressure. The magnet derives limit upon designated threshold of variable interval. The volt instantaneously determines variable differential of designated field of variance and instantaneous limit. The delta wave defines instantaneous measure.

POSTULATE:

Derivative upon sequential variance of determined inert threshold determines instantaneous variance upon derivative.

ENGINEERING:

Interval upon determined pressure defines instantaneous velocity upon determined field.

THEORY:

Instantaneous limit upon differential of static designation of congruent limit and invariable measure defines field.

ANALYSIS:

Derivative of static interval defines dimensional variance.

CONSLUSION:

The Vector Inert Radial defines congruent measure upon designated interval.

PROSPECT:

The Vector Inert Radial instantaneously derives pressure upon static limit.
